

Pandas Assignment

Deadline: 19-Jul-2026 11:59PM

Questions

- Using `.iloc[]`, select the first 5 rows and only the `full_name` and `department` columns.
 - Set `employee_id` as the index with `df.set_index("employee_id")`, then use `.loc[]` to retrieve the row for employee 1050.
- Select all employees with a salary greater than \$60,000.
 - Select all employees with a `performance_rating` of 5 AND more than 5 years of experience. (Hint: combine conditions with `&` and wrap each condition in parentheses.)
- Frequency table for `department`. Note anything strange in the output — why might departments that look the same get counted separately?
- Create a new column `department_clean` by stripping extra whitespace from `department`.
- Using `full_name` column create `first_name` and `last_name` columns.
 - Use `email` column to extract just the username (the part before the `@` is the username) into a new column.
- Using `department_clean`, group the data and find the average salary and the number of employees in each department. Which department has the highest average salary?
